Update of γ in $B^{\pm} \rightarrow [K^+K^-\pi^+\pi^-]_D h^{\pm}$ with external strong-phase inputs

Martin Tat

University of Oxford

LHCb-UK annual meeting, RAL

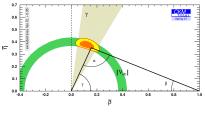

8th-10th January 2024

Introduction to γ and CP violation

- ullet CPV in SM is described by the Unitary Triangle, with angles lpha, eta, γ
- \bullet The angle $\gamma = \arg \Big(\frac{V_{ud} V_{ub}^*}{V_{cd} V_{cb}^*} \Big)$ is very important:
 - Negligible theoretical uncertainties: Ideal SM benchmark
 - 2 Accessible at tree level: Indirectly probe New Physics that enter loops
 - Ompare with a global CKM fit: Is the Unitary Triangle a triangle?

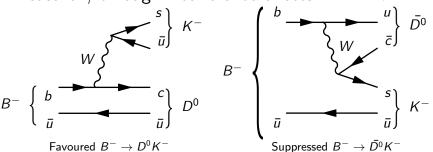

(a) Tree level: $\gamma = (72.1^{+5.4}_{-5.7})^{\circ}$

(b) Loop level: $\gamma = \left(65.5^{+1.1}_{-2.7}\right)^{\circ}$

CKMfitter Group (J. Charles et al.), Eur. Phys. J. C41, 1-131 (2005), updated results and plots available at: http://ckmfitter.in2p3.fr

Sensitivity through interference

Measure γ through interference effects in $B^{\pm} \rightarrow DK^{\pm}$

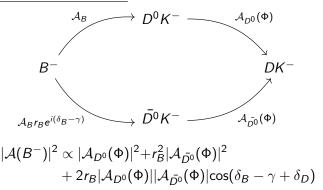

- ullet Superposition of D^0 and $ar{D^0}$
 - ullet Consider $D^0/ar{D^0}$ decays to the same final state, such as $D o K^+K^-$
- $b o u \bar{c}s$ and $b o c \bar{u}s$ interference o Sensitivity to γ $\mathcal{A}(B^-) = \mathcal{A}_B \left(\mathcal{A}_{D^0} + r_B e^{i(\delta_B \gamma)} \mathcal{A}_{\bar{D^0}} \right)$ $\mathcal{A}(B^+) = \mathcal{A}_B \left(\mathcal{A}_{\bar{D^0}} + r_B e^{i(\delta_B + \gamma)} \mathcal{A}_{D^0} \right)$

Multi-body D decays

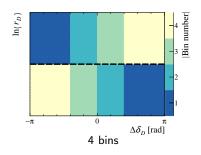

This talk: Discuss $D \to K^+K^-\pi^+\pi^-$, where interference effects vary across phase space

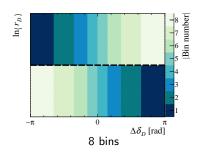

- Strong-phase difference δ_D is a function of phase space
- Compare yields of B^+ and B^- and determine the asymmetry in local phase space regions

Multi-body D decays

- \bullet Interpretation of γ from the multi-body charm decays require external inputs of the charm strong-phase differences
- Measure model-independent strong-phases at a charm factory, such as BESIII, using an optimised binning scheme

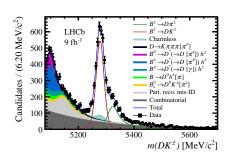

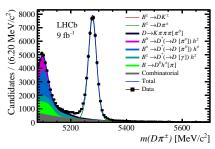

Eur. Phys. J. C 83, 547 (2023)

Phase-space binned $B^{\pm} \rightarrow [K^+K^-\pi^+\pi^-]_D K^{\pm}$

Fully charged final state \implies Highly suitable for LHCb

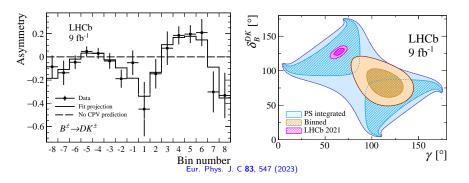

Eur. Phys. J. C 83, 547 (2023)

- $B^{\pm} \rightarrow [K^+K^-\pi^+\pi^-]_D h^{\pm}$ signal yield:
 - $B^{\pm} \to DK^{\pm}$: 3026 ± 38
 - $B^{\pm} \to D\pi^{\pm}$: 44349 ± 218

Phase-space binned $B^{\pm} \rightarrow [K^+K^-\pi^+\pi^-]_D K^{\pm}$

From the phase-space binned asymmetries, we obtain:

$$\gamma = (116^{+12}_{-14})^{\circ}$$

How will this evolve with model-independent BESIII inputs?

Reminder of formalism

Key free parameters in the fit:

- γ (obviously)
- r_B , δ_B : Hadronic parameters of $B^{\pm} \to DK^{\pm}$
- c_i , s_i : Charm strong-phase parameters

$B^\pm o DK^\pm$ yield in bin i

$$\hat{N}_{\pm i}^{\pm} = h_{B^{\pm}} \Big(F_i + r_B^2 F_{+i} + 2r_B \sqrt{F_+ F_{-i}} \Big(\cos(\delta_B \pm \gamma) c_i - \sin(\delta_B \pm \gamma) s_i \Big) \Big)$$

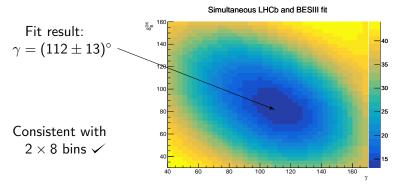

In principle straightforward: Fit B^\pm yields and extract γ

Reduce binning to 2 \times 4 bins to accommodate BESIII statistics: Current analysis uses 8 fb⁻¹ at ψ (3770), expect 20 fb⁻¹ in the near future

Cross check: Model-dependent fit of γ

Construct log-likelihood function using $B^{\pm} \to DK^{\pm}$ yields and model-predicted c_i and s_i :

$$\mathcal{L} = \frac{1}{2} \sum_{i} \left(\frac{N_i - \hat{N}_i}{\sigma_i} \right)^2$$

Strong-phase measurement at charm factories

Quick digression: Charm factories 101

Consider charm production at threshold: $e^+e^- o \psi(3770) o D^0ar{D}^0$

• $\psi(3770) o D^0 ar{D^0}$ decay conserves $\mathcal{C} = -1$

• If, for example, the tag is CP-even, $D_+ \to K^+ K^-$, the other D meson is forced into an CP-odd state

Strong-phase measurement at charm factories

Quick digression: Charm factories 101

Consider charm production at threshold: $e^+e^- o \psi(3770) o D^0 ar{D^0}$

CP-odd wave function and decay rate:

$$A(D_{-}) = A(D^{0}) - A(\bar{D^{0}}) \implies$$

$$|\mathcal{A}(D_{-})|^{2} = |\mathcal{A}(D^{0})|^{2} + |\mathcal{A}(\bar{D^{0}})|^{2} - 2|\mathcal{A}(D^{0})||\mathcal{A}(\bar{D^{0}})|\cos(\delta_{D})$$

With CP tags, one can directly access $\cos(\delta_D)$

Strong-phase measurement at charm factories

Quick digression: Charm factories 101

CP tags

$$N_i \propto K_i + K_{-i} \mp 2 \sqrt{K_i K_{-i}} c_i$$

Self-conjugate multi-body tags

$$N_{ij} \propto K_i K_{-j}^\prime + K_{-i} K_j^\prime - 2 \sqrt{K_i K_{-i} K_j^\prime K_{-j}^\prime} (c_i c_j^\prime + s_i s_j^\prime)$$

- **1** More than 10 different CP tags \implies Can measure c_i precisely
- ② Only $D o K_S^0 h^+ h^-$ tag is sensitive to $s_i \implies$ Worse s_i precision

Simultaneous fit of LHCb and BESIII bin yields

To include the effect of c_i and s_i from the BESIII measurement, perform a simultaneous fit:

$$\mathcal{L} = rac{1}{2} \sum_i \left(rac{ extsf{N}_i - \hat{ extsf{N}}_i}{\sigma_i}
ight)^2 + \mathcal{L}_{ extsf{BESIII}}$$

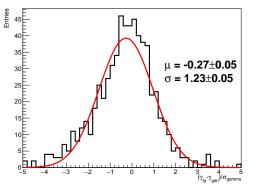

Why not simply assign a systematic uncertainty?

- \bullet Contribution of γ uncertainty from BESIII could be large, and may move the central value of γ
- 2 Uncertainties of s_i are expected to be very non-Gaussian, which could propagate into non-Gaussian uncertainties of γ

Simultaneous fit of LHCb and BESIII bin yields

Run toys using expected BESIII yields and bin yields from $B^{\pm} \rightarrow [K^+K^-\pi^+\pi^-]_D h^{\pm}$ paper:

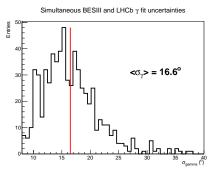

Simultaneous BESIII and LHCb γ fit pulls

Stable fit with minimal bias and small undercoverage

Simultaneous fit of LHCb and BESIII bin yields

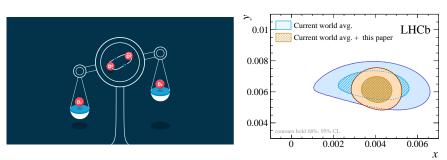

Study expected γ uncertainty, after correcting for coverage:

Conclusion from toy studies:

- Well behaved fit, with expected sensitivity of $\sigma(\gamma) = 16.6^{\circ}$
- Only small corrections to bias and coverage required
- **3** Will update γ result once BESIII measurement is released

The non-zero mass difference between D^0 and $\bar{D^0}$ was measured using the multi-body decay $D o K_S^0 \pi^+ \pi^-$

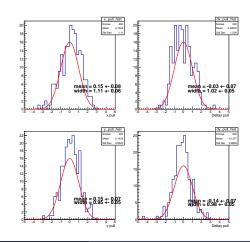

Phys. Rev. Lett 127, 111801 (2021)

Charm strong-phase differences were crucial for this measurement!

Ongoing charm mixing study of $D \to h^+ h^- \pi^+ \pi^-$ by Jairus Tristan Patoc

- ullet Prompt $D^{*+} o D^0 \pi^+$ sample
- Study $D^0 \rightarrow h^+h^-\pi^+\pi^-$
- Run 2 $(6 \, \text{fb}^{-1})$
- Expected yields are
 - $K^+K^-\pi^+\pi^-$: 4 million
 - $\pi^{+}\pi^{-}\pi^{+}\pi^{-}$: 12 million
- Current work:
 - Sensitivity and bias studies
 - Optimised selection

Mixing equations depend on x and y, but also c_i and s_i :

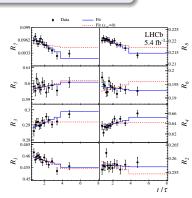

1. Charm mixing equations

$$\begin{array}{l} N_{D^0}(+i,\langle t\rangle_j) = K_{+i} - \sqrt{K_{+i}K_{-i}}\langle t\rangle_j(yc_i + xs_i) \\ N_{D^0}(-i,\langle t\rangle_j) = K_{-i} - \sqrt{K_{+i}K_{-i}}\langle t\rangle_j(yc_i - xs_i) \end{array}$$

- Fit the mixing equations
- Fit the ratio of mixing equations

2. Charm mixing ratio (bin-flip)

$$R_i = \frac{K_{+i} - \sqrt{K_{+i}K_{-i}} \langle t \rangle_j (yc_i + xs_i)}{K_{-i} - \sqrt{K_{+i}K_{-i}} \langle t \rangle_j (yc_i - xs_i)}$$

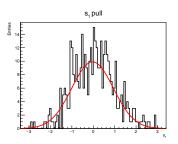

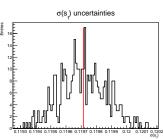

Alternative strategy: Fix x and y, and measure c_i and s_i

1. Charm mixing equations

$$\begin{array}{l} N_{D^0}(+i,\langle t\rangle_j) = K_{+i} - \sqrt{K_{+i}K_{-i}}\langle t\rangle_j(yc_i + xs_i) \\ N_{D^0}(-i,\langle t\rangle_j) = K_{-i} - \sqrt{K_{+i}K_{-i}}\langle t\rangle_j(yc_i - xs_i) \end{array}$$

- Two independent equations per bin, two observables per bin
- Similar statistical sensitivity to c_i and s_i , in contrast to BESIII

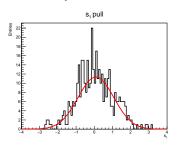

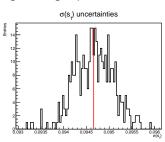

Can also use bin-flip method to fit s_i , but c_i must be fixed

2. Charm mixing ratio (bin-flip)

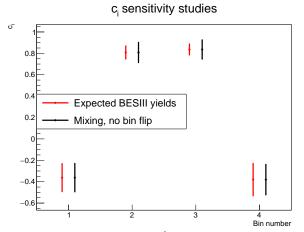

$$R_i = \frac{K_{+i} - \sqrt{K_{+i}K_{-i}} \langle t \rangle_j (yc_i + xs_i)}{K_{-i} - \sqrt{K_{+i}K_{-i}} \langle t \rangle_j (yc_i - xs_i)}$$

- Only one independent equation per bin
- Sensitivity found to be similar to fitting mixing equations directly

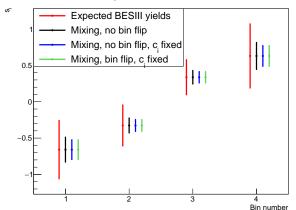

Sensitivity to c_i : Similar between BESIII and charm mixing at LHCb

- BESIII yields equivalent to 8 fb⁻¹ of ψ (3770)
- 4 million $D \to K^+K^-\pi^+\pi^-$ candidates in mixing analysis

Sensitivity to s_i : Significant improvements expected!

- ullet BESIII yields equivalent to 8 fb $^{-1}$ of $\psi($ 3770)
- 4 million $D \to K^+K^-\pi^+\pi^-$ candidates in mixing analysis

Summary and future prospects

Summary:

- Measurement of γ in $B^{\pm} \rightarrow [K^+K^-\pi^+\pi^-]_D h^{\pm}$ is ready to be combined with **model-independent** strong-phase inputs
- ② BESIII strong-phase inputs can be further constrained using charm-mixing measurements at LHCb, and provide comparable sensitivity to s_i

Summary and future prospects

Future prospects:

- Measurement is still statistically limited, and will be significantly improved with LHCb Upgrade I
- Additional BESIII data and charm-mixing measurements from LHCb will bring strong-phase systematics down further
- Oan extend this strategy to many more four-body modes
 - Studies of $D \to \pi^+\pi^-\pi^+\pi^-$ show similar results

Thanks for your attention!
